

Neural Net: Classify images of clothing

```
In [1]: # TensorFlow and tf.keras
import tensorflow as tf
from tensorflow import keras

# Helper libraries
import numpy as np
import matplotlib.pyplot as plt

print(tf.__version__)

2.1.0
```

Import the Fashion MNIST dataset

```
In [2]: fashion_mnist = keras.datasets.fashion_mnist

(train_images, train_labels), (test_images, test_labels) = fashion_mnist.load_data()
```

Loading the dataset returns four NumPy arrays:

1. The `train_images` and `train_labels` arrays are the training set—the data the model uses to learn.
2. The model is tested against the test set, the `test_images`, and `test_labels` arrays.

The images are 28x28 NumPy arrays, with pixel values ranging from 0 to 255. The labels are an array of integers, ranging from 0 to 9. These correspond to the class of clothing the image represents:

Label	Class
0	T-shirt/top
1	Trouser
2	Pullover
3	Dress
4	Coat
5	Sandal
6	Shirt
7	Sneaker
8	Bag
9	Ankle boot

Each image is mapped to a single label. Since the class names are not included with the dataset, store them here to use later when plotting the images:

```
In [3]: class_names = ['T-shirt/top', 'Trouser', 'Pullover', 'Dress', 'Coat',
                        'Sandal', 'Shirt', 'Sneaker', 'Bag', 'Ankle boot']
```

Explore the data

```
In [4]: train_images.shape
```

```
Out[4]: (60000, 28, 28)
```

Likewise, there are 60,000 labels in the training set:

```
In [5]: len(train_labels)
```

```
Out[5]: 60000
```

Each label is an integer between 0 and 9:

```
In [6]: train_labels
```

```
Out[6]: array([9, 0, 0, ..., 3, 0, 5], dtype=uint8)
```

There are 10,000 images in the test set. Again, each image is represented as 28 x 28 pixels:

```
In [7]: test_images.shape
```

```
Out[7]: (10000, 28, 28)
```

And the test set contains 10,000 images labels:

```
In [8]: len(test_labels)
```

```
Out[8]: 10000
```

Preprocess the data

The data must be preprocessed before training the network. If you inspect the first image in the training set, you will see that the pixel values fall in the range of 0 to 255:

```
In [9]: plt.figure()
plt.imshow(train_images[0])
plt.colorbar()
plt.grid(False)
plt.show()
```

Scale these values to a range of 0 to 1 before feeding them to the neural network model. To do so, divide the values by 255. It's important that the training set and the testing set be preprocessed in the same way:

```
In [10]: train_images = train_images / 255.0
test_images = test_images / 255.0
```

To verify that the data is in the correct format and that you're ready to build and train the network, let's display the first 25 images from the training set and display the class name below each image.

```
In [11]: plt.figure(figsize=(10,10))
for i in range(25):
    plt.subplot(5,5,i+1)
    plt.xticks([])
    plt.yticks([])
    plt.grid(False)
    plt.imshow(train_images[i], cmap=plt.cm.binary)
    plt.xlabel(class_names[train_labels[i]])
plt.show()
```

Build the model

Building the neural network requires configuring the layers of the model, then compiling the model.

Set up the layers

The basic building block of a neural network is the layer. Layers extract representations from the data fed into them. Hopefully, these representations are meaningful for the problem at hand.

Most of deep learning consists of chaining together simple layers. Most layers, such as `tf.keras.layers.Dense`, have parameters that are learned during training.

```
In [14]: model = keras.Sequential([
          keras.layers.Flatten(input_shape=(28, 28)),
          keras.layers.Dense(128, activation='relu'),
          keras.layers.Dense(10)
        ])
```

The first layer in this network, `tf.keras.layers.Flatten`, transforms the format of the images from a two-dimensional array (of 28 by 28 pixels) to a one-dimensional array (of $28 * 28 = 784$ pixels). Think of this layer as unstacking rows of pixels in the image and lining them up. This layer has no parameters to learn; it only reformats the data.

After the pixels are flattened, the network consists of a sequence of two `tf.keras.layers.Dense` layers. These are densely connected, or fully connected, neural layers. The first Dense layer has 128 nodes (or neurons). The second (and last) layer returns a logits array with length of 10. Each node contains a score that indicates the current image belongs to one of the 10 classes.

Compile the model

Before the model is ready for training, it needs a few more settings. These are added during the model's compile step:

1. Loss function —This measures how accurate the model is during training. You want to minimize this function to "steer" the model in the right direction.
2. Optimizer —This is how the model is updated based on the data it sees and its loss function.
3. Metrics —Used to monitor the training and testing steps. The following example uses accuracy, the fraction of the images that are correctly classified.

```
In [15]: model.compile(optimizer='adam',
                      loss=tf.keras.losses.SparseCategoricalCrossentropy(from_logits=True),
                      metrics=['accuracy'])
```

Train the model

Training the neural network model requires the following steps:

1. Feed the training data to the model. In this example, the training data is in the `train_images` and `train_labels` arrays.
2. The model learns to associate images and labels.
3. You ask the model to make predictions about a test set—in this example, the `test_images` array.
4. Verify that the predictions match the labels from the `test_labels` array.

Feed the model

To start training, call the `model.fit` method—so called because it "fits" the model to the training data:

```
In [16]: model.fit(train_images, train_labels, epochs=10)

Train on 60000 samples
Epoch 1/10
60000/60000 [=====] - 3s 45us/sample - loss: 0.4972 - a
ccuracy: 0.8260
Epoch 2/10
60000/60000 [=====] - 2s 40us/sample - loss: 0.3743 - a
ccuracy: 0.8645
Epoch 3/10
60000/60000 [=====] - 2s 31us/sample - loss: 0.3362 - a
ccuracy: 0.8773
Epoch 4/10
60000/60000 [=====] - 2s 30us/sample - loss: 0.3122 - a
ccuracy: 0.8860
Epoch 5/10
60000/60000 [=====] - 2s 30us/sample - loss: 0.2974 - a
ccuracy: 0.8907
Epoch 6/10
60000/60000 [=====] - 2s 30us/sample - loss: 0.2804 - a
ccuracy: 0.8966
Epoch 7/10
60000/60000 [=====] - 2s 30us/sample - loss: 0.2691 - a
ccuracy: 0.9000
Epoch 8/10
60000/60000 [=====] - 2s 30us/sample - loss: 0.2576 - a
ccuracy: 0.9044
Epoch 9/10
60000/60000 [=====] - 2s 31us/sample - loss: 0.2457 - a
ccuracy: 0.9079
Epoch 10/10
60000/60000 [=====] - 2s 31us/sample - loss: 0.2393 - a
ccuracy: 0.9109

Out[16]: <tensorflow.python.keras.callbacks.History at 0x2369f2bb5c8>
```

As the model trains, the loss and accuracy metrics are displayed. This model reaches an accuracy of about 0.91 (or 91%) on the training data.

Evaluate accuracy

Next, compare how the model performs on the test dataset:

```
In [17]: test_loss, test_acc = model.evaluate(test_images, test_labels, verbose=2)

print('\nTest accuracy:', test_acc)

10000/10000 - 0s - loss: 0.3230 - accuracy: 0.8875

Test accuracy: 0.8875
```

It turns out that the accuracy on the test dataset is a little less than the accuracy on the training dataset. This gap between training accuracy and test accuracy represents overfitting. Overfitting happens when a machine learning model performs worse on new, previously unseen inputs than it does on the training data. An overfitted model "memorizes" the noise and details in the training dataset to a point where it negatively impacts the performance of the model on the new data.

Make predictions

With the model trained, you can use it to make predictions about some images. The model's linear outputs, logits. Attach a softmax layer to convert the logits to probabilities, which are easier to interpret.

```
In [18]: probability_model = tf.keras.Sequential([model,
                                                tf.keras.layers.Softmax()])
```

```
In [19]: predictions = probability_model.predict(test_images)
```

Here, the model has predicted the label for each image in the testing set. Let's take a look at the first prediction:

```
In [20]: predictions[0]
```

```
Out[20]: array([1.5785666e-08, 2.7332296e-09, 3.9596319e-08, 9.5935836e-11,
                2.0788450e-08, 5.6048372e-04, 8.7946477e-09, 9.4149848e-03,
                7.6001406e-08, 9.9002433e-01], dtype=float32)
```

A prediction is an array of 10 numbers. They represent the model's "confidence" that the image corresponds to each of the 10 different articles of clothing. You can see which label has the highest confidence value:

```
In [21]: np.argmax(predictions[0])
```

```
Out[21]: 9
```

So, the model is most confident that this image is an ankle boot, or `class_names[9]`. Examining the test label shows that this classification is correct:

```
In [22]: test_labels[0]
```

```
Out[22]: 9
```

Graph this to look at the full set of 10 class predictions.

```
In [23]: def plot_image(i, predictions_array, true_label, img):
    predictions_array, true_label, img = predictions_array, true_label[i], img[i]
    plt.grid(False)
    plt.xticks([])
    plt.yticks([])

    plt.imshow(img, cmap=plt.cm.binary)

    predicted_label = np.argmax(predictions_array)
    if predicted_label == true_label:
        color = 'blue'
    else:
        color = 'red'

    plt.xlabel("{} {:2.0f}% ({})".format(class_names[predicted_label],
                                        100*np.max(predictions_array),
                                        class_names[true_label]),
              color=color)

def plot_value_array(i, predictions_array, true_label):
    predictions_array, true_label = predictions_array, true_label[i]
    plt.grid(False)
    plt.xticks(range(10))
    plt.yticks([])
    thisplot = plt.bar(range(10), predictions_array, color="#777777")
    plt.ylim([0, 1])
    predicted_label = np.argmax(predictions_array)

    thisplot[predicted_label].set_color('red')
    thisplot[true_label].set_color('blue')
```

Verify predictions

With the model trained, you can use it to make predictions about some images.

Let's look at the 0th image, predictions, and prediction array. Correct prediction labels are blue and incorrect prediction labels are red. The number gives the percentage (out of 100) for the predicted label.

```
In [24]: i = 0
    plt.figure(figsize=(6,3))
    plt.subplot(1,2,1)
    plot_image(i, predictions[i], test_labels, test_images)
    plt.subplot(1,2,2)
    plot_value_array(i, predictions[i], test_labels)
    plt.show()
```

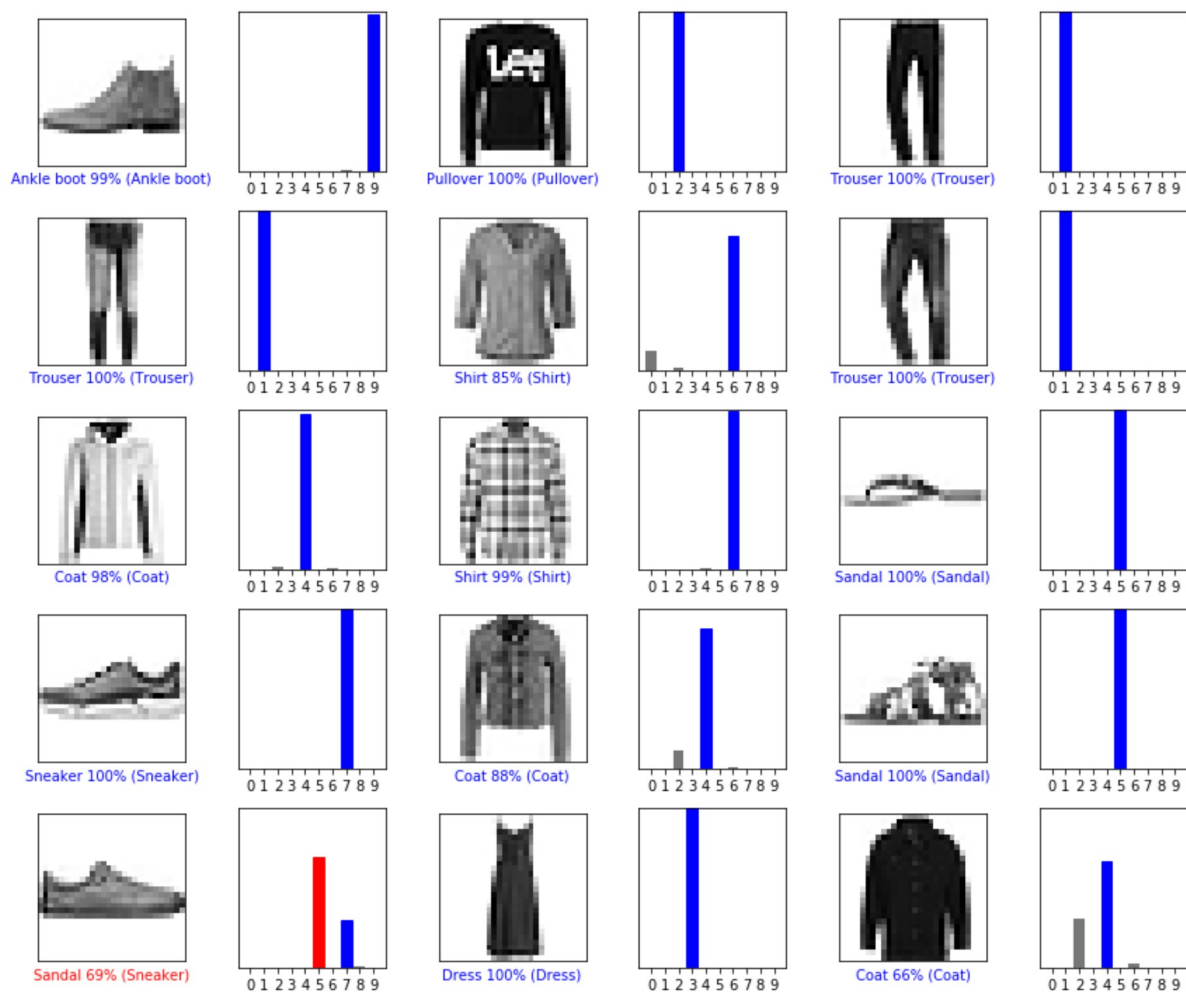

```
In [25]: i = 12
plt.figure(figsize=(6,3))
plt.subplot(1,2,1)
plot_image(i, predictions[i], test_labels, test_images)
plt.subplot(1,2,2)
plot_value_array(i, predictions[i], test_labels)
plt.show()
```

Let's plot several images with their predictions. Note that the model can be wrong even when very confident.

```
In [26]: # Plot the first X test images, their predicted labels, and the true labels.
# Color correct predictions in blue and incorrect predictions in red.
num_rows = 5
num_cols = 3
num_images = num_rows*num_cols
plt.figure(figsize=(2*2*num_cols, 2*num_rows))
for i in range(num_images):
    plt.subplot(num_rows, 2*num_cols, 2*i+1)
    plot_image(i, predictions[i], test_labels, test_images)
    plt.subplot(num_rows, 2*num_cols, 2*i+2)
    plot_value_array(i, predictions[i], test_labels)
plt.tight_layout()
plt.show()
```

Use the trained model

Finally, use the trained model to make a prediction about a single image.

```
In [28]: # Grab an image from the test dataset.
img = test_images[1]

print(img.shape)
```

(28, 28)

tf.keras models are optimized to make predictions on a batch, or collection, of examples at once. Accordingly, even though you're using a single image, you need to add it to a list:

```
In [29]: # Add the image to a batch where it's the only member.
img = (np.expand_dims(img,0))

print(img.shape)

(1, 28, 28)
```

Now predict the correct label for this image:

```
In [30]: predictions_single = probability_model.predict(img)

print(predictions_single)

[[4.41627844e-06  6.71915526e-14  9.99492168e-01  5.44959000e-12
  4.01117431e-04  7.28553468e-11  1.02180966e-04  9.05462736e-17
  2.73194770e-13  1.23505711e-13]]
```

```
In [31]: plot_value_array(1, predictions_single[0], test_labels)
_ = plt.xticks(range(10), class_names, rotation=45)
```

```
In [32]: np.argmax(predictions_single[0])
```

Out [32]: 2

And the model predicts a label as expected.

This tutorial uses the Fashion MNIST dataset which contains 70,000 grayscale images in 10 categories. The images show individual articles of clothing at low resolution (28 by 28 pixels), as seen here:

Here, 60,000 images are used to train the network and 10,000 images to evaluate how accurately the network learned to classify images. You can access the Fashion MNIST directly from TensorFlow. Import and load the Fashion MNIST data directly from TensorFlow
